4D

Stuff

Lumigraph – Capture

- Convert images into a solid 3D model

- Render from images and model

Lumigraph – Image Effects

Can model effects such as:

- parallax
- occlusion
- translucency
- refraction
- highlights
- reflections

Unstructured Lumigraph

- What if the images aren't sampled on a regular 2D grid?
- Can still re-sample rays
- Ray weighting becomes more complex [Heigl *et al.*, DAGM'99]
- Unstructured Lumigraph [Buehler *et al.*, SIGGRAPH'2000]
- Deep blending [Hedman *et al.*, SG Asia 2018]
- FVS [Riegler & Koltun, ECCV'2020]

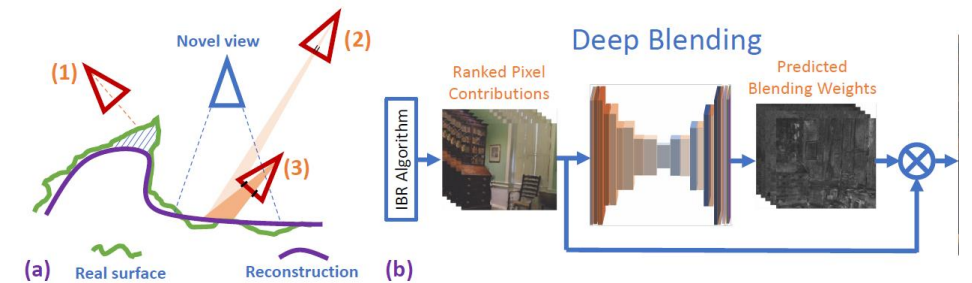

Figure 3. Drawing triangles of neighboring projected camera centers and approximating scene geometry by one plane for the whole scene, for one camera triple or by several planes for one camera triple.

Surface Light Fields

- [Wood et al, SIGGRAPH 2000]
- Turn 4D parameterization around:
 - image @ every surface pt.
- Leverage coherence:
 - compress radiance fn (BRDF * illumination) after rotation by n

Surface Light Fields

Facebook's new Surround 360 video cameras let you move around inside live-action scenes

The freedom of VR with the fidelity of real life

By [Nick Statt](#) | [@nickstatt](#) | Apr 19, 2017, 1:15pm EDT

Facebook today announced the second generation of its [Surround 360 video camera](#) design, and this time the company is serious about helping potential customers purchase it as an actual product. The Surround 360, which Facebook unveiled last year as an [open-source spec guide for others to build off of](#), has been upgraded as both a larger, more capable unit and a smaller, more portable version.

Dual camera
phone

Input burst of 34 color-and-depth photos,
captured in 34.0 seconds

Our 3D panorama (showing color, depth, and a 3D effect),
generated in 34.7 seconds.

Our work enables practical and casual 3D capture with regular dual camera cell phones. Left: A burst of input color-and-depth image pairs that we captured with a dual camera cell phone at a rate of one image per second. Right: 3D panorama generated with our algorithm in about the same time it took to capture. The geometry is highly detailed and enables viewing with binocular and motion parallax in VR, as well as applying 3D effects that interact with the scene, e.g., through occlusions (right).

Google Photos cinematic effect

Jamie Aspinall

Product Manager, Google Photos

Published Dec 15, 2020

Relive the moment with Cinematic photos

Cinematic photos help you relive your memories in a way that feels more vivid and realistic—so you feel like you’re transported back to that moment. To do this, we use machine learning to predict an image’s depth and produce a 3D representation of the scene—even if the original image doesn’t include depth information from the camera. Then we animate a virtual camera for a smooth panning effect—just like out of the movies.

Real-World Normal Map Capture for Nearly Flat Reflective Surfaces

Bastien Jacquet¹, Christian Häne¹, Kevin Köser^{12*}, Marc Pollefeys¹

ETH Zürich¹
Zürich, Switzerland

GEOMAR Helmholtz Centre for Ocean Research²
Kiel, Germany

Abstract

Although specular objects have gained interest in recent years, virtually no approaches exist for markerless reconstruction of reflective scenes in the wild. In this work, we present a practical approach to capturing normal maps in real-world scenes using video only. We focus on nearly planar surfaces such as windows, facades from glass or metal, or frames, screens and other indoor objects and show how normal maps of these can be obtained without the use of an artificial calibration object. Rather, we track the reflections of real world straight lines while moving with a hand held

Figure 1. Real-world glass reflection. Notice that reflection in different windows on the same facade can appear very different due to minor deformations and normal variations. Our goal is to capture normal maps of real windows to faithfully reproduce this effect.

Figure 14.18 Animating still pictures (Chuang, Goldman et al. 2005) © 2005 ACM. (a) The input still image is manually segmented into (b) several layers. (c) Each layer is then animated with a different stochastic motion texture (d) The animated layers are then composited to produce (e) the final animation

Animating Pictures

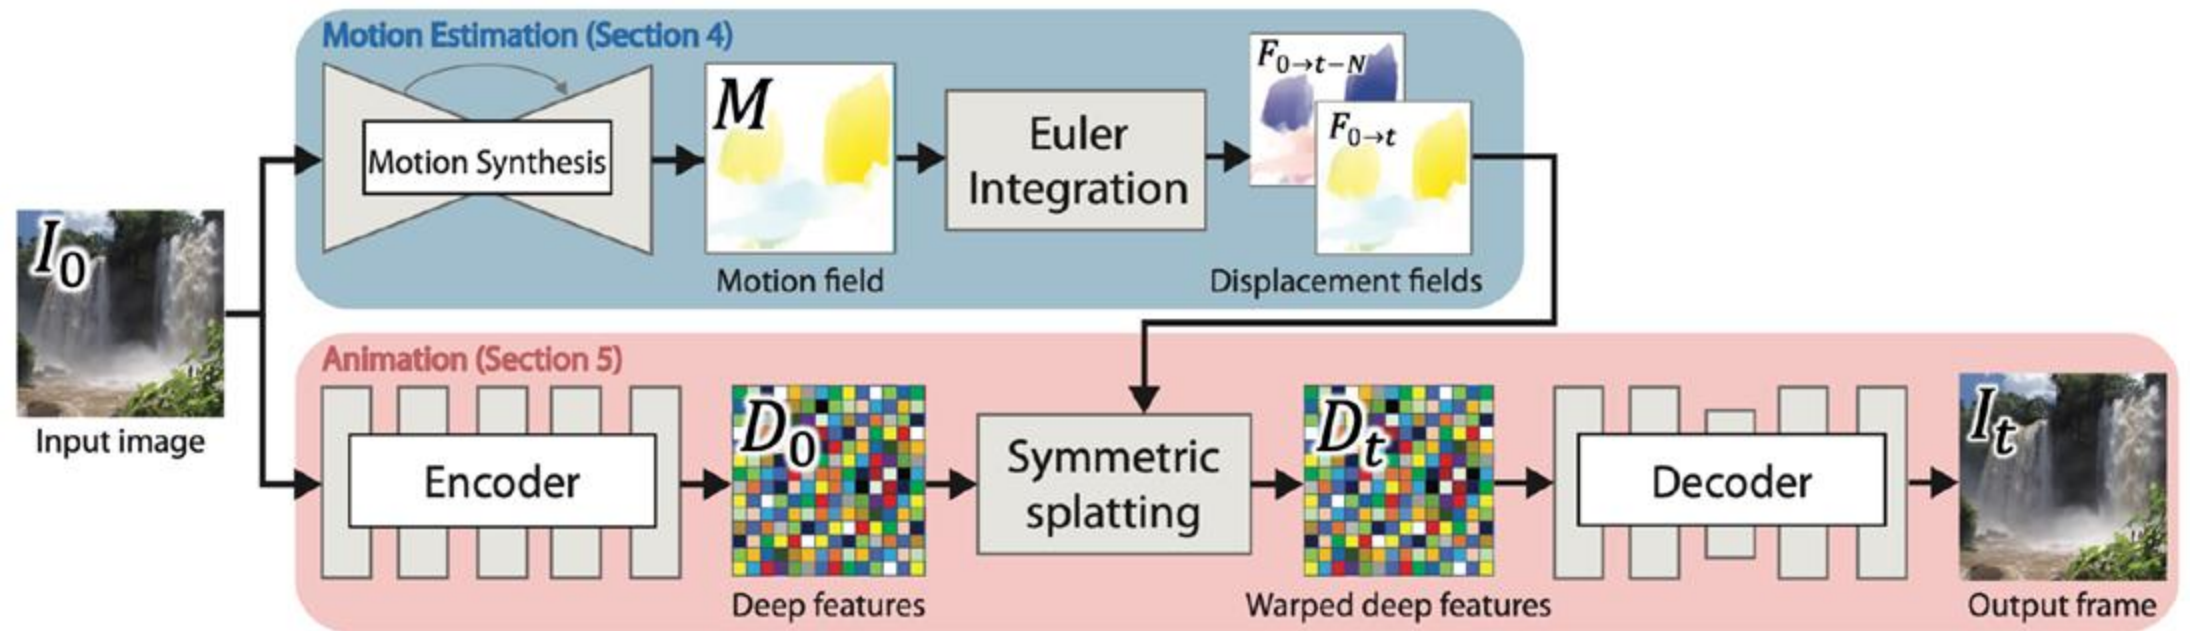

Figure 2: **Overview:** Given an input image I_0 , our motion estimation network predicts a motion field M . Through Euler integration, M is used to generate future and past displacement fields $F_{0 \rightarrow t}$ and $F_{0 \rightarrow t-N}$, which define the source pixel locations in all other frames t . To animate the input image using our estimated motion, we first use a feature encoder network to encode the image as a feature map D_0 . This feature map is warped by the displacement fields (using a novel symmetric splatting technique) to produce the corresponding warped feature map D_t . The warped features are provided to the decoder network to create the output video frame I_t .

Animating Pictures

Figure 3: **Deep warping**: Above: Naïve splatting of RGB pixels results in increasingly large unknown regions over time, shown in magenta. Below: For the same frames, our deep warping approach synthesizes realistic texture in these unknown regions.

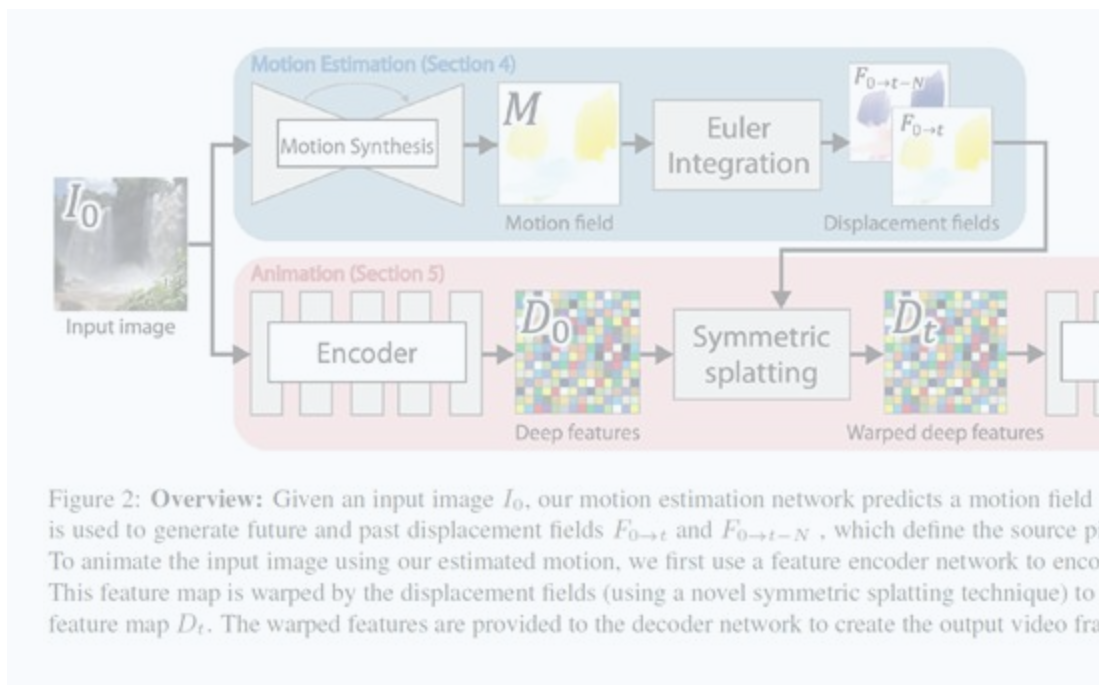

Figure 4: **Seamless looping**: An illustrated example of how seamless loops are created. Two feature videos are created by warping D_0 . The first, V_f , contains the result of integrating the motion field M , resulting in a video starting with the input image and animating into the future. The second, V_p , instead uses $-M$, resulting in a video starting in the past and ending with the input frame. These two videos typically contain complementary unknown regions (shown in magenta). Before decoding, we combine the two

Stable View Synthesis [Riegler and Koltun]

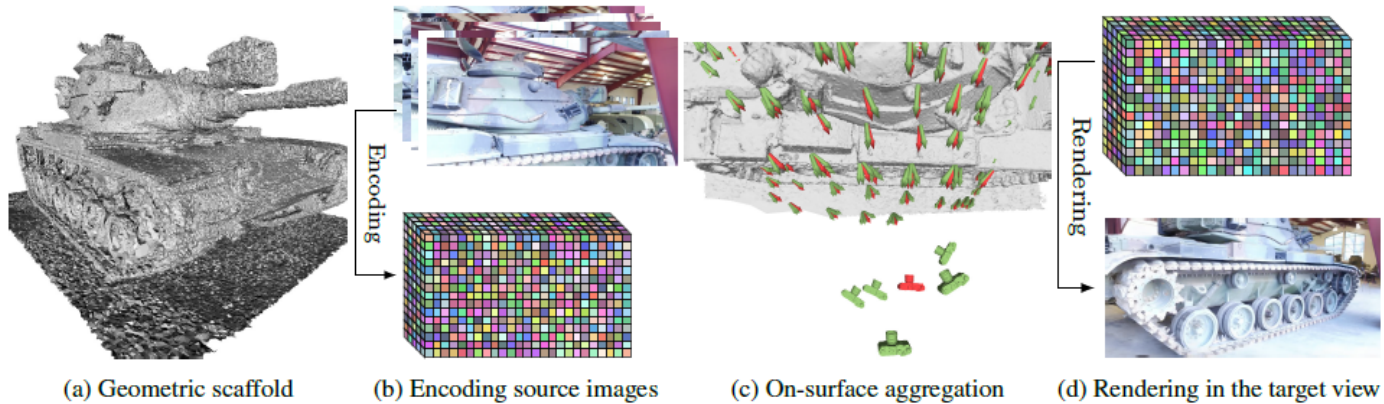

Figure 2: **Overview of Stable View Synthesis.** (a) A geometric scaffold of the scene is constructed using structure-from-motion, multiple-view stereo, and meshing. (b) All source images are encoded into feature tensors via a convolutional network. (c) Given a new target view (red camera), feature vectors from the source images are aggregated along rays from the geometric scaffold. Red arrows map 3D points to the target view, green arrows show feature aggregation. (d) The output image in the target view is rendered from a tensor of synthesized features.

Figure 3: **On-surface aggregation.** A 3D point x on the geometric scaffold Γ is seen in a set of source images. Each such image contributes a feature vector f_k along a ray v_k .

Your book is coming along! I read over the monodepth section and the neural rendering section. Both look good to me. They come across as fair and comprehensive. The neural rendering section is a bit like covering Waterloo in the middle of the battle. You can describe the position and movements of the different pieces, but everything is in motion and it's not clear what will survive, what will be remembered, and what shape this will all settle into.

Best,
Vladlen

NeRF++

NeRF++: ANALYZING AND IMPROVING NEURAL RADIANCE FIELDS

Figure 5: For 360° captures of unbounded scenes, NeRF's parameterization of space either models only a portion of the scene, leading to significant artifacts in background elements (a), or models the full scene and suffers from an overall loss of detail due to finite sampling resolution (b).

Figure 6: NeRF++ applies different parameterizations for scene contents inside and outside the unit sphere.

- *Adapt volume to camera configuration (MPI ~ volumetric grid)*

NeRV and NeRD (2021)

(a) Input images of the scene under unconstrained varying (known) lighting conditions

(b) Output renderings from novel viewpoints and lighting conditions

Figure 1: We optimize a Neural Reflectance and Visibility Field (NeRV) 3D representation from a set of input images of a scene illuminated by known but unconstrained lighting. Our NeRV representation can be rendered from novel views under arbitrary lighting conditions not seen during training. Here, we visualize example input data and renderings for two scenes. The first two output rendered images for each scene are from the same viewpoint, each illuminated by a point light at a different location, and the last image is from a different viewpoint under a random colored illumination.

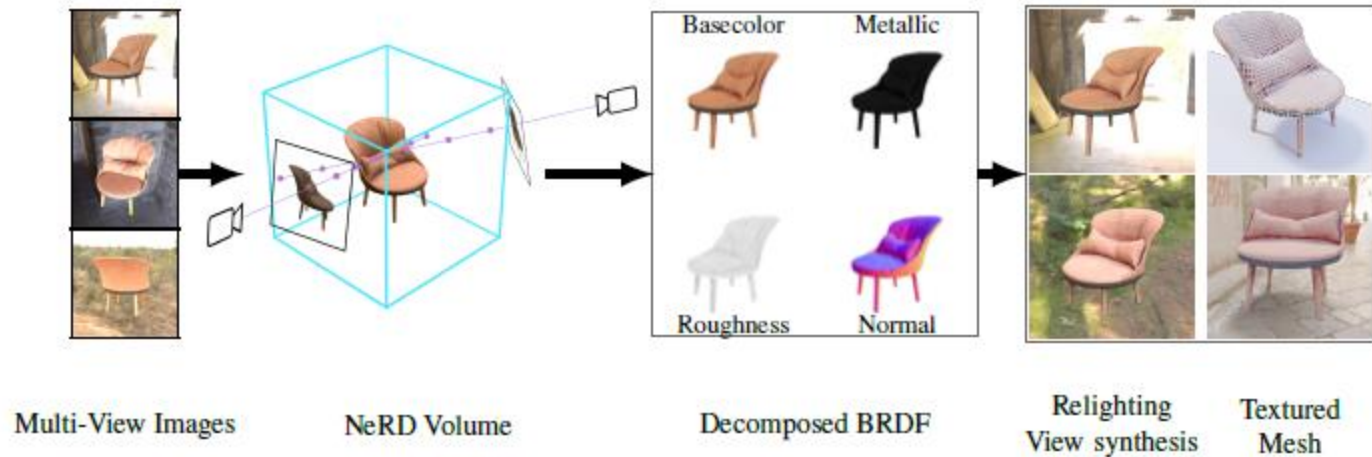

Figure 1: **Neural Reflectance Decomposition.** Multiple views of an object under varying or fixed illumination are encoded into the NeRD volume. During the encoding process, information provided by all samples is decomposed into geometry, spatially-varying BRDF parameters and a rough approximation of the incident illumination in a globally consistent way. This decomposition can be easily extracted and re-rendered under a novel illumination condition in real-time.

Real-time Neural Based Rendering

NeX: Real-time View Synthesis with Neural Basis Expansion

Suttisak Wizadwongsa*

{suttisak.w_s19, pakkapor

Figure 1: (a) Each pixel in NeX multiplane image is decomposed into reflectance coefficients $k_1 \dots k_n$. A linear combination of these coefficients produces the final color value. (b, c) show our method's ability to handle effects such as the reflection on the silver spoon.

FastNeRF: High-Fidelity Neural Rendering at 200FPS

... wrapping up ...

Outline

- Image-Based Rendering
 - Lumigraphs, Light Fields, Sprites with Depth, and Layers
- Virtual Viewpoint Video
- 360° and 3D Video
- 3D Photos
- Reflections and transparency
- Neural rendering

3D for Image-Based Rendering & Novel View Synth.

- Many real-world, highly used applications in:
 - Video Processing
 - Computational Photography
 - Virtual Reality
- Many remaining challenges
 - Specularities and reflections
 - Textureless and thin object

Thank you
